Databases

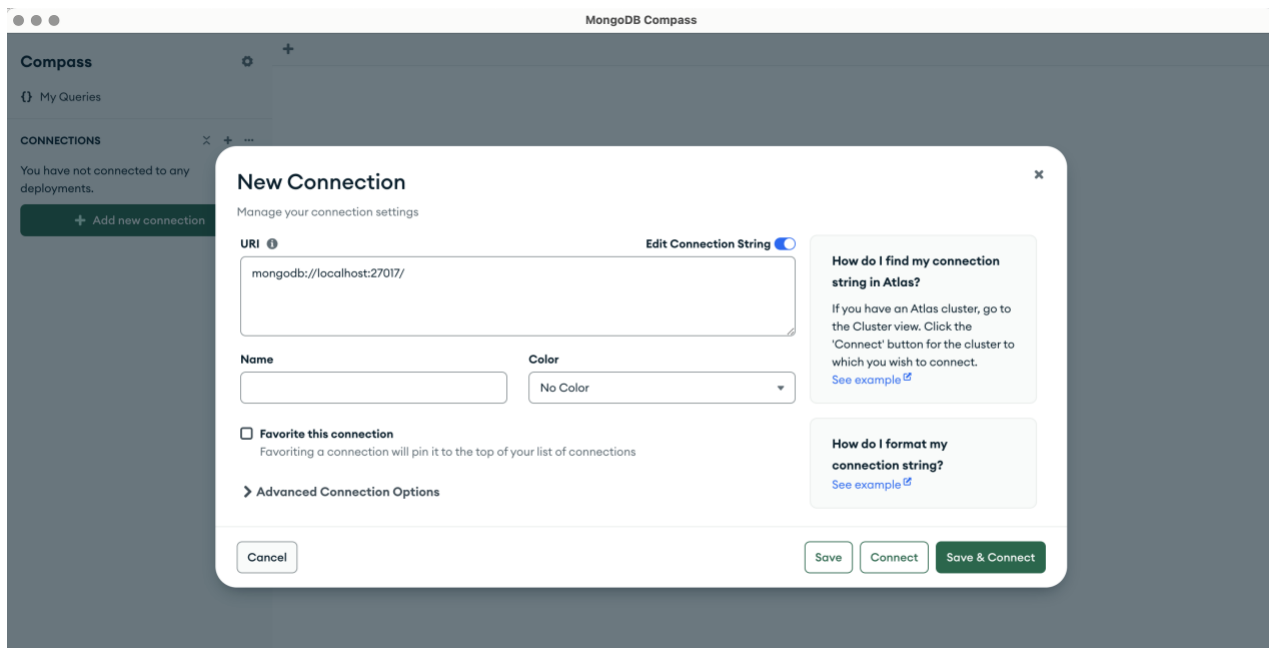

TABLE OF CONTENTS

<i>MongoDB Setup</i>	1
Connecting localhost	1
Creating a new database and collection	1
Importing data from CSV File	2
The Person Collection	2
<i>Updating Documents</i>	3
Updating Address field	3
Update Favourite field	4
Update Neighbour field	5
Example Object After All Updates	6
<i>Document Data Model</i>	7
<i>Queries</i>	8
Display all persons' name and their ages in years	8
Group Persons by their favourite drink and return average age of each group	9
Display the average age of people who like Hiking	10
Display the total number of people from each City and sort it in ascending order by total number of people	11
Display name of person(s) whose neighbour is neighbour C	12

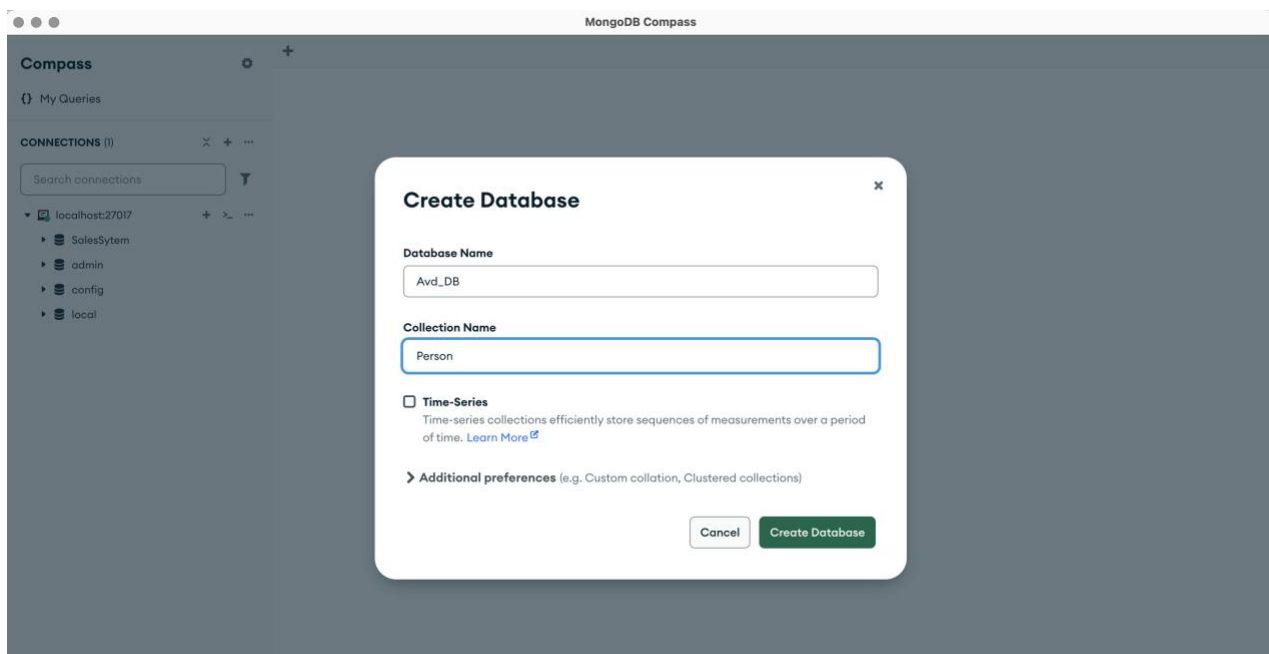

MONGODB SETUP

MongoDB setup using MongoDB Compass. In a NoSQL model, a single collection can be used to store all data to simplify data retrieval and reduce complexity. Therefore, all the data is imported straight from CSV file.

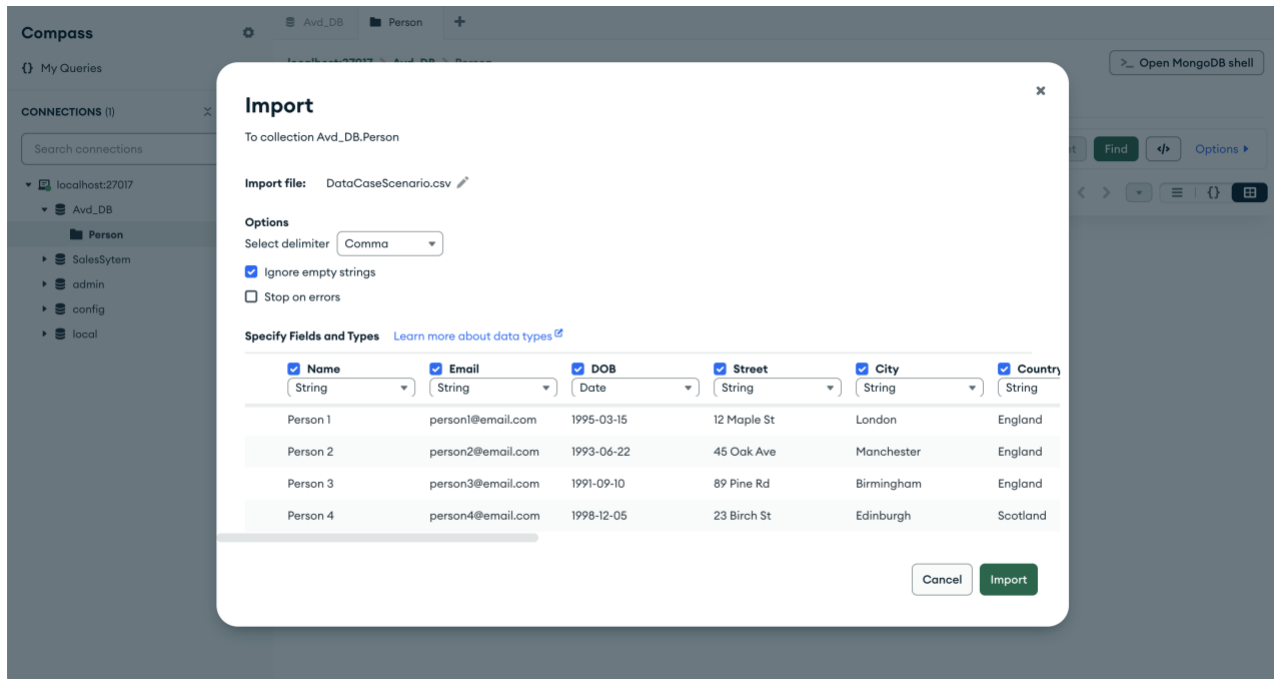

CONNECTING LOCALHOST

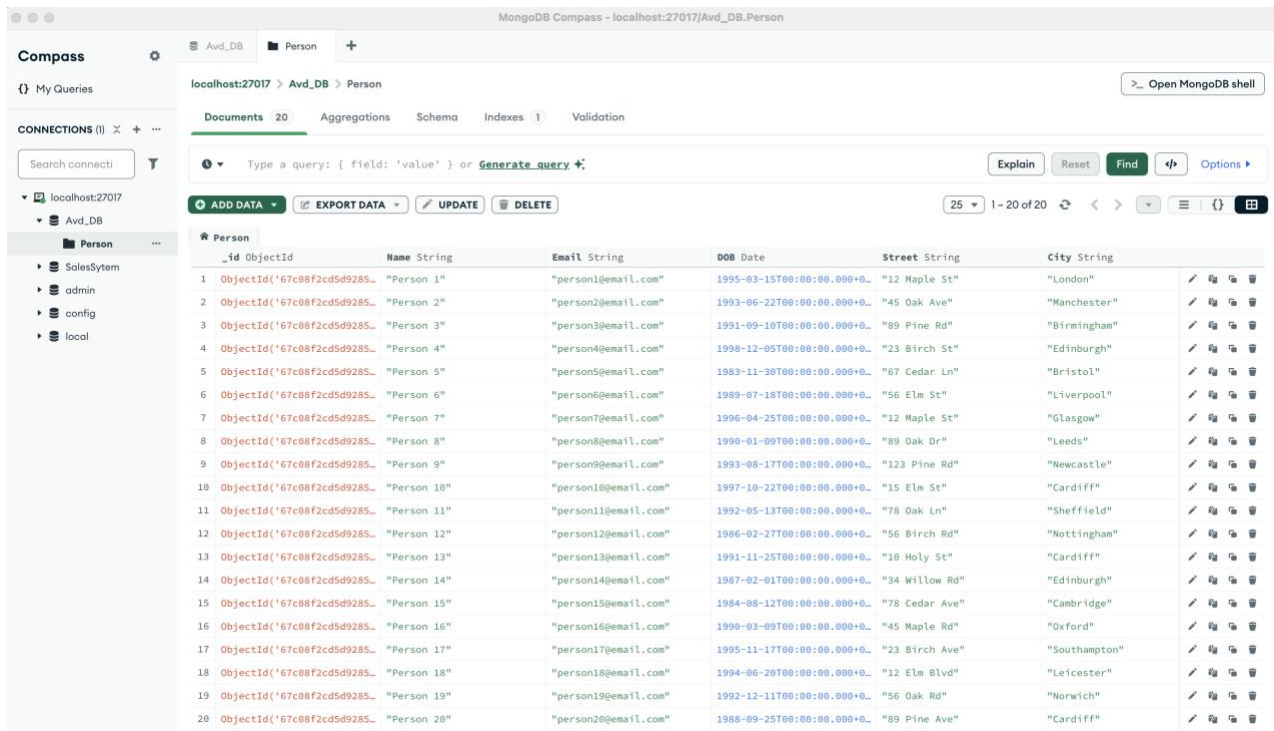

CREATING A NEW DATABASE AND COLLECTION

IMPORTING DATA FROM CSV FILE

THE PERSON COLLECTION

UPDATING DOCUMENTS

The data is transformed into a more structured design to improve efficiency:

- The imported CSV file had a flat structure, which made address details, favourite items and neighbours' information scattered as separate fields. By grouping related data, the database is more readable and organised, reducing complexity.
- With this design, queries become more efficient, as MongoDB can fetch entire objects instead of selecting multiple fields when retrieving data. This also improves the indexing performance of traversing the nested documents rather than scanning unrelated fields.

UPDATING ADDRESS FIELD

Instead of having different fields for `Street`, `City`, `Country` and `Zip Code`, the address details are reconstructed into a nested object called `Address`.

Update 20 documents

UPDATE FAVOURITE FIELD

Instead of having different fields for *Favourite Book*, *Favourite Drink*, and *Favourite Activity*, all favourite types are reconstructed into a nested object called *Favourite*.

UPDATE NEIGHBOUR FIELD

The neighbour information of name and email is stored into an array of objects called *Neighbour* to work efficiently with two neighbour objects.
